

# Introduction to Artificial Intelligence

## COMP 3501 / COMP 4704-4

### Lecture 13: Supervised Learning

---

Prof. Nathan Sturtevant

## Today

---

- Learning
- Decision Trees

## Learning

---

- Any aspect of an agent can (potentially) be improved through learning
- Depends on:
  - What component to be improved
  - Prior knowledge of the agent
  - Representation used for data & the component
  - What feedback is available for learning

## Types of learning

---

- Unsupervised learning
  - Learning about data by looking at its features
  - No specific feedback from users
  - Usually entails clustering data

## Types of learning

---

- Reinforcement learning
  - Agents with sensors experience the world
  - As they act they receive positive and negative rewards
  - The agent then learns value of (sensor) states

## Types of learning

---

- Supervised learning
  - Agent is given example input and correct output
  - Goal is to build general model that will produce correct output on novel input

## Types of learning

---

- Semi-supervised learning
  - Some labeled examples in data set
  - Some mislabeled examples
  - Learn generalized model

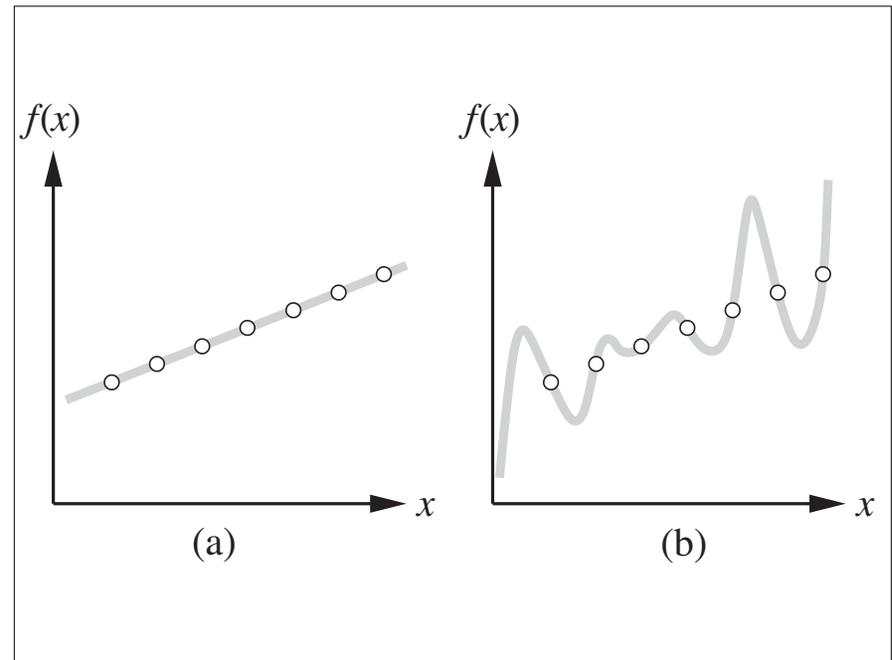

## Supervised learning

---

- Given a *training set* of  $N$  example input & outputs
  - $(x_1, y_1), (x_2, y_2), \dots (x_N, y_N)$
  - Where each  $y_i$  comes from an unknown function
    - $y_i = f(x_i)$
  - Discover a function  $h$  such that  $h(x_i) \approx f(x_i)$
- Think of  $h$  as a hypothesis, and we are searching for the “best” hypothesis

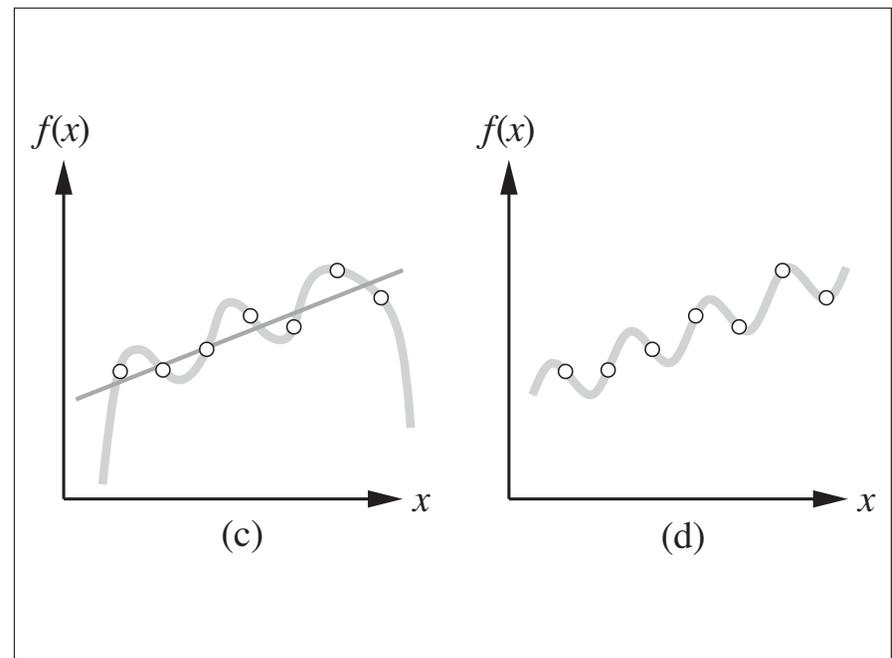

## Supervised learning

- All available data is usually broken into:
  - Training set: exclusively used for study & training
  - Test set: exclusively used for testing
- Ensures that the learning generalizes from training data to test data
  - Want to avoid overfitting data

## Ockham's razor

- Given multiple possible hypotheses that explain the data, choose the simplest one
  - 1st degree polynomial is probably better than a 3rd degree polynomial
- Decision isn't always clear

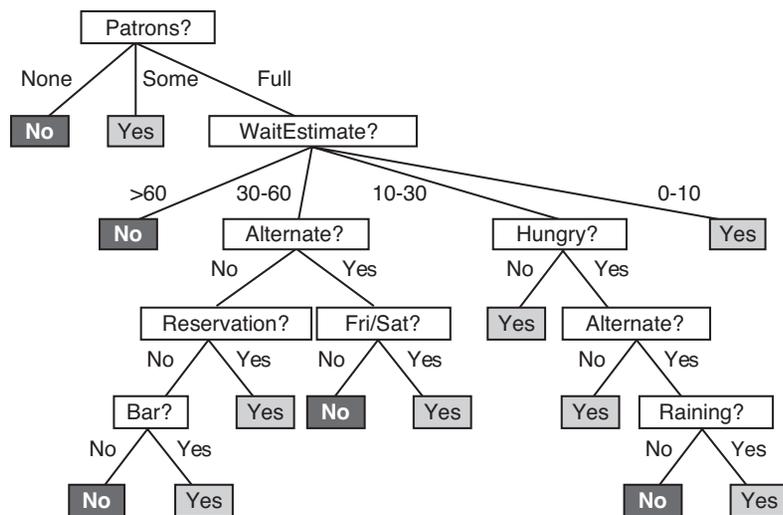

## Decision Trees

- A decision tree is a simple classifier
- Training input:
  - Data points with a set of attributes
- Classifier output:
  - Can be boolean or have multiple outputs
  - Each leaf stores an “answer”

## Example

- Should we wait for a table at a restaurant?
- Possible attributes:
  - Alternate restaurant nearby?
  - Is there a bar to wait in?
  - Is it Friday or Saturday?
  - How hungry are we?
  - How busy is the restaurant?
  - How many people in the restaurant?

## Representation

- The states which reach each outcome can be represented by written as the disjunction (or) of each possible path of decisions
- What about a decision tree for N boolean inputs:
  - Are more than N/2 inputs true?

## General Approach

- Greedy approaches work well
  - Choose the category that divides into the best sub-problems

## Example

| Example  | Attributes |            |            |            |             |               |             |            |                |               | Goal            |
|----------|------------|------------|------------|------------|-------------|---------------|-------------|------------|----------------|---------------|-----------------|
|          | <i>Alt</i> | <i>Bar</i> | <i>Fri</i> | <i>Hun</i> | <i>Pat</i>  | <i>Price</i>  | <i>Rain</i> | <i>Res</i> | <i>Type</i>    | <i>Est</i>    | <i>WillWait</i> |
| $X_1$    | <i>Yes</i> | <i>No</i>  | <i>No</i>  | <i>Yes</i> | <i>Some</i> | <i>\$\$\$</i> | <i>No</i>   | <i>Yes</i> | <i>French</i>  | <i>0-10</i>   | <i>Yes</i>      |
| $X_2$    | <i>Yes</i> | <i>No</i>  | <i>No</i>  | <i>Yes</i> | <i>Full</i> | <i>\$</i>     | <i>No</i>   | <i>No</i>  | <i>Thai</i>    | <i>30-60</i>  | <i>No</i>       |
| $X_3$    | <i>No</i>  | <i>Yes</i> | <i>No</i>  | <i>No</i>  | <i>Some</i> | <i>\$</i>     | <i>No</i>   | <i>No</i>  | <i>Burger</i>  | <i>0-10</i>   | <i>Yes</i>      |
| $X_4$    | <i>Yes</i> | <i>No</i>  | <i>Yes</i> | <i>Yes</i> | <i>Full</i> | <i>\$</i>     | <i>Yes</i>  | <i>No</i>  | <i>Thai</i>    | <i>10-30</i>  | <i>Yes</i>      |
| $X_5$    | <i>Yes</i> | <i>No</i>  | <i>Yes</i> | <i>No</i>  | <i>Full</i> | <i>\$\$\$</i> | <i>No</i>   | <i>Yes</i> | <i>French</i>  | <i>&gt;60</i> | <i>No</i>       |
| $X_6$    | <i>No</i>  | <i>Yes</i> | <i>No</i>  | <i>Yes</i> | <i>Some</i> | <i>\$\$</i>   | <i>Yes</i>  | <i>Yes</i> | <i>Italian</i> | <i>0-10</i>   | <i>Yes</i>      |
| $X_7$    | <i>No</i>  | <i>Yes</i> | <i>No</i>  | <i>No</i>  | <i>None</i> | <i>\$</i>     | <i>Yes</i>  | <i>No</i>  | <i>Burger</i>  | <i>0-10</i>   | <i>No</i>       |
| $X_8$    | <i>No</i>  | <i>No</i>  | <i>No</i>  | <i>Yes</i> | <i>Some</i> | <i>\$\$</i>   | <i>Yes</i>  | <i>Yes</i> | <i>Thai</i>    | <i>0-10</i>   | <i>Yes</i>      |
| $X_9$    | <i>No</i>  | <i>Yes</i> | <i>Yes</i> | <i>No</i>  | <i>Full</i> | <i>\$</i>     | <i>Yes</i>  | <i>No</i>  | <i>Burger</i>  | <i>&gt;60</i> | <i>No</i>       |
| $X_{10}$ | <i>Yes</i> | <i>Yes</i> | <i>Yes</i> | <i>Yes</i> | <i>Full</i> | <i>\$\$\$</i> | <i>No</i>   | <i>Yes</i> | <i>Italian</i> | <i>10-30</i>  | <i>No</i>       |
| $X_{11}$ | <i>No</i>  | <i>No</i>  | <i>No</i>  | <i>No</i>  | <i>None</i> | <i>\$</i>     | <i>No</i>   | <i>No</i>  | <i>Thai</i>    | <i>0-10</i>   | <i>No</i>       |
| $X_{12}$ | <i>Yes</i> | <i>Yes</i> | <i>Yes</i> | <i>Yes</i> | <i>Full</i> | <i>\$</i>     | <i>No</i>   | <i>No</i>  | <i>Burger</i>  | <i>30-60</i>  | <i>Yes</i>      |

**Figure 18.3** Examples for the restaurant domain.

## Recursive splitting

- Choosing and assigning to a node in the decision tree to an attribute produces a smaller decision tree problem
  - When all examples have the same outcome; done.
  - If examples are split, choose another attribute
  - If there are no examples, set default value
  - If there are no attributes left, there are conflicting examples (use the best classification)

## Measuring the best splitting

- The choice for splitting is defined in terms of entropy
  - Entropy measures uncertainty
    - A fair coin has 1-bit of entropy
    - A 4-sided die has 2 bits of entropy
- Entropy of a random variable  $V$  with values  $v_k$  and probabilities  $P(v_k)$  is:

$$-\sum_k P(v_k) \log_2 P(v_k)$$

## Entropy examples

$$-\sum_k P(v_k) \log_2 P(v_k)$$

- Entropy of a fair coin:
  - $-(0.5 \log_2(0.5) + 0.5 \log_2(0.5)) = 1$
- Entropy of a coin which is heads 99% of the time:
  - $-(0.99 \log_2(0.99) + 0.01 \log_2(0.01)) \approx 0.08$

## Entropy & Decision tree learning

- Let  $B(q)$  be the entropy of a boolean variable with probability  $q$  of being true
- Assume the training set has  $p$  positive and  $n$  negative examples
  - $H(\text{Goal}) = B(p / p+n)$
  - This is the entropy of the problem being decided

## Entropy & Decision tree learning

- Measure the change in entropy after splitting on a variable  $A$

$$\text{Remainder}(A) = \sum_{k=1}^d \frac{p_k + n_k}{p + n} B\left(\frac{p_k}{p_k + n_k}\right)$$

- The gain of splitting on  $A$  is:

$$\text{Gain}(a) = B\left(\frac{p}{p+n}\right) - \text{Remainder}(A)$$

- $\text{Gain}(\text{Patrons}) = 0.541$  bits
- $\text{Gain}(\text{Type}) = 0$  bits

## Class Example

- Everyone provide an example for what we should do tonight.
- Choices:
  - Go out with friends
  - Stay in with friends
  - Stay in and work/sleep
- Features
  - HW: high, medium, low
  - Tired: high, medium, low
  - (other features?)
